Glossary

Social Network Analysis: graphical, statistical and visualization metrics, algorithms and techniques for analysing structural data that can be represented as nodes and relations. Social network analysis is also referred to as network analysis, dynamic network analysis, network science, SNA, DNA.

Social Media: data generated by an on-line social networking tools such as Twitter, Facebook or Foursquare. Social media networks are networks derived from social media data such as the Twitter retweet network. Social media are also referred to as on-line sources, open-source, e-media.

Dynamic Networks: networks that vary through time. An example is the network of who talks to whom within a company by day. Dynamic networks are also referred to as temporal networks, time variant networks, and dynamical networks.

Spatial Networks: networks embedded in space such that each node has one or more locations at which it occurs. An example is the network of who interacts with whom among political activists such that each activist is also linked to the locations at which they have taken part in demonstrations. Spatial networks are also referred to as geo-spatial networks, geo-intelligence networks, geographical networks, networks through space, and spatially embedded networks.

***Length: Long Essays:** 3600-6000 words or 20,000 -40,000 characters with space (approx. 5-10 printed pages) **Illustrations** are welcome, this will be mentioned in the guidelines

Meta-Networks: a network of networks, in which there are generally multiple classes of nodes, and multiple classes of link. Meta-networks are also referred to as high-dimensional networks, and geo-temporally embedded meta-networks.

Definition

ORA: A network analysis toolkit for graphical, statistical and visual analytics on both social networks and high dimensional networks that can vary by time and/or space. ORA is a full function network analytics package that supports the user in creating, importing, exporting, manipulating, editing, analysing, comparing, contrasting, and forecasting changes in one or more networks. ORA is a multi-platform network toolkit that can operate in stand-alone mode or as a service within a web architecture.

ORA ID card:

- * tool name, title - ORA
- * creation year - 1995
- * author – Kathleen M. Carley
- * scope – general
- * copyright – academic student version, commercial full professional version
- * type – program
- * size limits – over 1 million nodes in batch
- * platforms – PC, LINUX, and MAC
- * programming language – Java GUI and C++ backend
- * orientation – multi-disciplinary

Introduction

ORA is a network analytic tool developed by CMU and Netanomics, that allows the user to fuse, analyze, visualize, and forecast behavior given network data. Using ORA the user can reason about networks at the node, group, or network level. ORA includes a wide range of capabilities that supports multiple types of analyses; e.g., the user can analyze a social network using standard social network metrics; examine geo-temporal networks; identify key actors, key topics and hot spots of activity; identify communities, sub-groups and patterns of interest; examine changes in which nodes are key; examine changes in group membership, and so on. ORA is designed to support the analysis networks that vary in size (e.g. from small to large networks), type (e.g., the networks can be social, communication, semantic, task or other), and the networks can be high dimensional, aka meta-networks, that are dynamic and may be embedded in geographic regions.

***Length: Long Essays:** 3600-6000 words or 20,000 -40,000 characters with space (approx. 5-10 printed pages) **Illustrations** are welcome, this will be mentioned in the guidelines

Key Points

There are several ways in which ORA differs from other social network toolkits. First, it actively supports high dimensional network data, often referred to as meta-network data, including changes in such data through time and embedded in space. Thus ORA has not just one-mode metrics, but two-mode, and multi-mode networks. Many of these metrics and algorithms are only available in ORA such as measures of cognitive demand, redundancy and the fuzzy grouping algorithm – FOG. Second, ORA supports analysis on very large network data sets. There is both a gui version of ORA and a batch mode version – the latter of which has been used with networks with 10^6 nodes. Third, ORA is interoperable with a large number of other tools. For example, data in csv, tsv, UCINET, or Twitter json formats and many other formats can be directly imported. Further, ORA can export to Google Earth, or to KML files, thus enabling interoperation with GIS tools. Fourth, ORA has been designed to reduce training time and effort on the part of the user. For example, output is organized by topic which enables the user to select a topic and then all the major metrics used for that topic are automatically computed and printed to a web-page. This means that the user does not have to remember what metrics to run. As another example, common sequences that are done by users are automated and occur with a single keystroke. Fifth and finally, ORA has an integrated on-line help system, tool tips, QuickStart Guide (Carley, 2013), users-guide (Carley et al., 2013a), and an associated Google-groups to provide help. Moreover, two text-books provide guidance in network analysis and show those analyses in ORA (Everton, 2012; McCulloh et al., 2013).

Historical Background

ORA was originally developed as a network toolkit to support reasoning about changes in network within organizations from a meta-network perspective. This led to the organizational management report which not only identifies key actors but also assesses the level of shared situation awareness, individuals who might be over or underworked, and other factors that can lead to organizational problems such as the identification of insider threats. ORA has evolved enormously from this beginning.

ORA was extended to support link analysis in addition to social network analysis, for complex socio-cultural systems. This led to improved visualization, data entry, and multi-mode metrics. This also led to support for reasoning about the network in context, placing networks on maps, and visualizing the trails that led to the formation of network ties.

ORA was extended to support semantic network analysis and to enable the user to build networks from text. That led to the inclusion of new rhetorical based network metrics, and interoperation with text-mining software.

ORA was extended to support network pattern of life analysis. This led to the inclusion of spectral analytics for networks and network change detection.

Today, ORA supports full spectrum network analytics and visualization for small to very large networks. It has evolved into a widely used tool that is interoperable with many other technologies. It supports network analytics across a large number of domains, and has been used in both theoretical and very applied contexts.

***Length: Long Essays:** 3600-6000 words or 20,000 -40,000 characters with space (approx. 5-10 printed pages) **Illustrations** are welcome, this will be mentioned in the guidelines

ORA

ORA is intended to be a comprehensive analytic and visualization engine for network analytics and forecasting that transcends traditional disciplinary boundaries as it supports standard social network analysis, link analysis, geo-network analysis, and dynamic network analysis. The algorithms in ORA are thus from a large number of fields (Carley & Pfeffer, 2012). In a similar vein, ORA supports data entry from and export to many other tools common in fields where network analysis is used. ORA supports analysis of many types of networks – e.g., social networks, social-media networks, communication networks, activity networks, and semantic networks. As such, there are many metrics in ORA that are specialized to certain types of network data – e.g., geo-temporal networks. ORA is organized by the questions the user asks, not the metrics. As such, common workflows are automated and all metrics relevant to a particular question are automatically included in a report providing the network answer to the question of interest. Visual analytics are a key feature in ORA which employs both graphical, statistical and visual analytic algorithms to help the user assess, visualize and forecast behavior for social networks or high dimensional networks that can be dynamic or spatially situated. ORA supports 2D and 3D network visualization, geo-spatial network visualization, heat maps, loom or trail visualization, nodel (a node variant of wordl) and chart visualization capabilities. Finally, ORA supports reasoning about and with networks through the inclusion of basic matrix algebra operations, algorithms for generating synthetic networks, search and selection procedures, and simple simulation engines and comparative statics for examining the potential impact of change. The basic interface to ORA and part of several reports are shown in Figure 1.

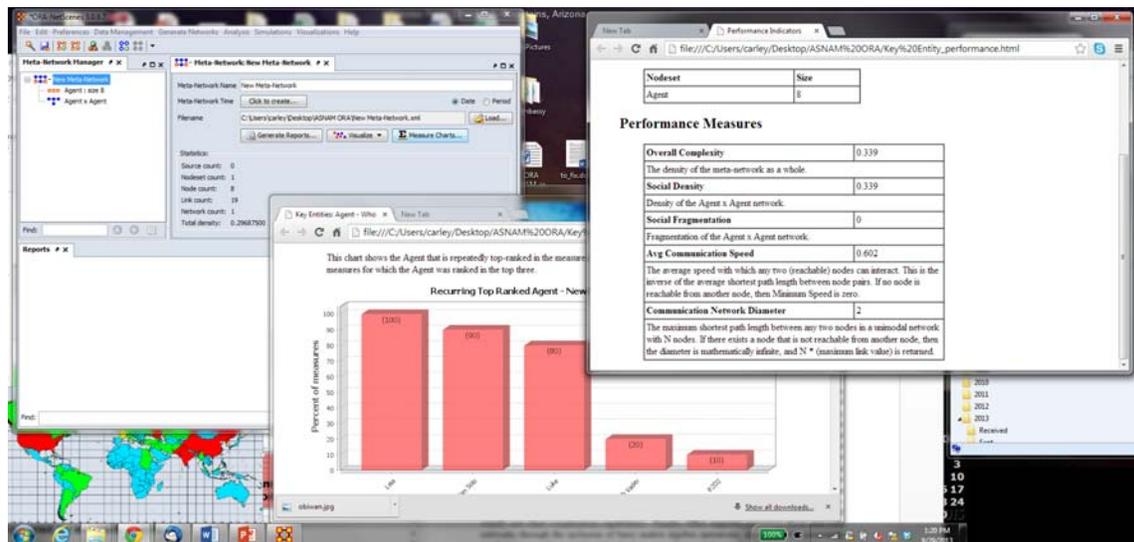

Figure 1. Illustration of ORA in operation.

What can be done in ORA?

Using ORA the analyst can identify key actors, key topics, key locations, characterize and visualize networks, assess changes in the networks and the key actors, key topics and key locations, visualize trends, identify patterns in the networks, examine the networks and key actors, key topics and key locations in terms of where they are by using the geo-spatial mapping functions, and multiple other tasks. Within ORA there are wizards for many multi-step

***Length: Long Essays:** 3600-6000 words or 20,000 -40,000 characters with space (approx. 5-10 printed pages) **Illustrations** are welcome, this will be mentioned in the guidelines

functions such as data importing, cleaning a visualization, and running common metrics. Many of these wizards lead the user through a set of decision when analyzing the data and generating reports. A list of the reports, functions and generators in ORA is in Table 1. The system is organized by questions that the user might ask of the data, and many common workflows are built in to reduce time to do standard analyses. For example, a typical network question is what are the key nodes? The Key Entity report automatically runs various centrality metrics and 2-mode networks for identifying key nodes. Which metrics are run depends on the type of entity – i.e., whether the nodes is a who, what, where, why or how. Figure 1 shows parts of the Key Entity report.

ORA can also go beyond node analysis. For example, it contains a wide range of grouping, clustering, pattern and community detection algorithms. These are available in the Locate Group report. Moreover, within the visualizer the user can color nodes by the groups they are in. ORA also supports change detection and spectral analysis for network metrics at the node and graph level. Using these techniques dynamic data can be assessed and changes and regularities in the way network metrics and nodes behave over time can be characterized.

User Control and Awareness

***Length: Long Essays:** 3600-6000 words or 20,000 -40,000 characters with space (approx. 5-10 printed pages) **Illustrations** are welcome, this will be mentioned in the guidelines

There are an increasing number of people who want to analyze networks; however, many of them have had little training in network analytics. This can lead them to make errors in analysis without realizing it such as identifying a nodes centrality when the “network” contains multiple types of links and nodes. ORA tries to minimize this by providing more user guidance, not allowing functions that are known to not be applicable, and making the user be explicit about what node class a node is in and the nature of the relationship. Moreover, ORA makes explicit whether the results are based on the status of the underlying network such as whether it is binary or symmetrized. Studies show that ORA results map onto other common widely used network analysis tools when the user manipulates the data to match the way the other tool alters the data by default (Wei et al. 2011).

High End Visualization

ORA enables the user to interact with the data visually in a number of ways. Many of these are shown in Figure 2. One of the keys is that the visualizer and the data editor are linked so that a change in one effects a change in the other. Thus the user can directly enter or edit data in the visualizer, or the user can directly see the impact on the network image as nodes are merged or deleted in the editor. In addition, standard graphing tools are used in reports for things such as pie charts, spider graphs, scatter plots and histograms.

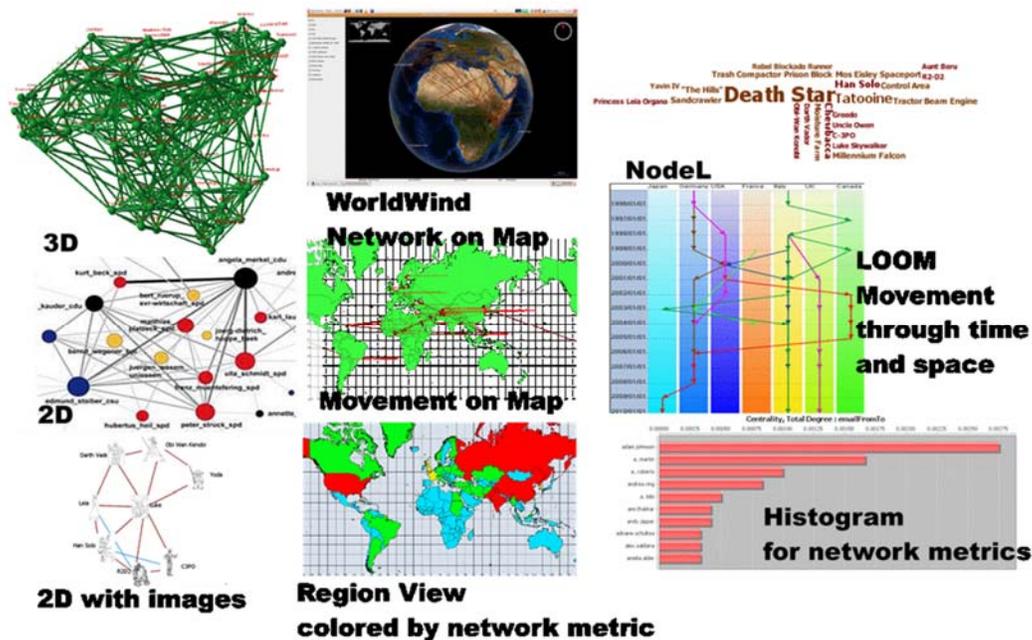

Figure 2. Illustrative Visualization Capabilities

Temporal Analysis and Geo-Temporal Analysis

A unique feature of ORA is that it enables the user to examine networks as they change through time, and the movement of networks through space. Many of the reports, if the user has two time periods, automatically do a comparison. In the visualizer the network over time allows the user to step through changes in the network in movie like fashion, and view changes over time for measures or nodes of the user’s choice.

***Length: Long Essays:** 3600-6000 words or 20,000 -40,000 characters with space (approx. 5-10 printed pages) **Illustrations** are welcome, this will be mentioned in the guidelines

For multi-time period data spectral analysis and change detection are available (McCulloh et al., 2012). Spectral analysis supports the user in assessing the regularities and anomalies in temporal network data. Graph or node level metrics can be examined over time and the “patterns of life” identified, such as the drop in twitter activity at 4 am or an increase in the centrality of a team lead in email traffic immediately after a group meeting. Change detection is a forensic technique that supports the user in identifying when a change in a dynamic network occurred that led to the current signal.

There are two different techniques for what-if analysis that support reasoning about change. The first of these is the immediate impact report where the user can select a set of nodes or links to remove and then a static comparison is run between the original network and the hypothetical new network. The second technique is the near term impact report where ORA calls the network simulator Construct already instantiated with data from the network being analyzed. Then a simple simulation based virtual experiment is run.

When the network is geo-temporal it is often useful to think in terms of trails. The trail format captures data of the form who/what was where when. An example would be information on people moving through space. Another example, in which the where is virtual, would be authors publishing papers in different journal through time. In this case the “where” is the journal. ORA supports changing data from trails to networks and networks to trails. Moreover, it supports direct analysis of trails in the visualization sub-tool – LOOM. There are also specialized reports, one that identifies the geo-temporal clusters using a trial clustering algorithm (Gullapalli and Carley, 2013).

Big Data Analytics

ORA is designed to support the analysis of networks varying in size through a set of wizards and optimizations that change how the system operates depending on the size of the data. Recently approximation algorithms have been added such as the k-centrality algorithms (Pfeffer and Carley, 2012). Special features for very big data include allowing the user to choose to not run slow metrics such as betweenness, and automated grouping prior to visualization for very large networks. The professional version of ORA can be run either through the interface or from the command line. All metrics have been optimized for sparse matrices. Tests have shown ORA capably of running, through command line or on very large multi-processor machines analytics on networks with 10^6 nodes and 10^7 links.

Interoperability

ORA is designed to work synergistically with other applications. To begin with there is the data to model workflow (Carley et al., 2007) designed so that the user could step through extracting networks from texts (AutoMap, Carley et al., 2013c), then analyze those networks (ORA, Carley et al., 2013a), then simulate changes in those networks (Construct, Carley et al., 2012a; Carley et al., 2009b). This interoperability is made possible through the use of DyNetML a variant of GraphML that support large scale dynamic network of high dimensional data. The format is completely open. This workflow has been recently improved and the entire process increased in speed (Carley et al., 2012c). Secondly ORA can import from and export to a number of formats. For example, data can be imported in a number of ways, including from Excel, CSV, TSV, UCINET, Pajek, Analyst Notebook, PenLink, Personal Brain, GraphML, shape files, and various twitter JSON formats. Images can be saved in pdf, tiff, jpeg, svg, and a proprietary editable format. Shape files in KML can be exported from the geo-spatial

***Length: Long Essays:** 3600-6000 words or 20,000 -40,000 characters with space (approx. 5-10 printed pages) **Illustrations** are welcome, this will be mentioned in the guidelines

visualizer which can also port to NASA WorldWind and Google Earth. Reports are in HTML and work with most browsers, CSV and often PDF formats are also available.

Key Applications

ORA has been used in a wide number of contexts. Indeed new applications appear frequently. Selected applications are listed in Table 2. The items in Table 2 are meant to be illustrative not exhaustive. In essence, the use of ORA is only limited by the user's imagination. The meta-network flexibility admits analysis of many kinds of data, from social networks of who interacts with whom, to Twitter networks, to studies of who is critical and what did they do where and when. Illustrative examples of how ORA has been used in various contexts include: assessment of covert activity (Carley et al., 2009a), citation analysis (Kas et al., 2012), social media analysis (Carley et al, 2013b), public health (Merrill et al., 2012), hospital safety outcomes (Effken et al., 2013), structure of ethnic violence (van Holt et al., 2012) and terror groups (Kenney et al., 2012).

Future Directions

ORA is evolving in several ways. These include supported platforms, data entry and manipulation, algorithms, big-data analytics, statistical reasoning, and interoperation.

Platforms: Currently there is both a free student version and a more comprehensive professional COTS system able to handle larger data faster and with better 3d and geo-spatial capabilities. Multi-platform versions for the Mac, and Linux are in beta-version. An enterprise version that supports scripting and a web-version for operation in Ozone exist and are being extended.

Data Entry and Manipulation: ORA is currently being extended to directly read-in additional JSON formats for Twitter. New optimized workflows for merging and deleting nodes for multiple networks at once are in development. Further,

Algorithms: Currently there are over 150 metrics and 20 grouping algorithms in ORA. New incremental and approximation metrics, and new group level measures are being added.

Big Data Analytics: ORA has been optimized for large-scale sparse matrices. The scripting version can handle 10^6 nodes. Metrics are ordered by their speed so the user can choose through the interface to run only fast measures, to run all but the slowest measures, or to run all measures. Currently, new metrics to support even faster processing are being implemented. These include the incremental metrics for closeness (Kas et al, 2013a) and betweenness (Kas et al, 2013b). In addition, since ORA supports dynamic analysis, the current system is being refactored to support improved speed for handling multiple time periods at once. Again the incremental metrics support temporal analysis as well.

Statistical Reasoning: ORA currently has a version of QAP and MRQAP. The MRQAP routine is being extended to allow the user to specify and run multiple models with a scripting approach. Further, an ERGM module for ORA is currently under development. Finally, most reports provide some guidance as to whether the metrics observed are within or beyond the bounds expected given a normal distribution; comparison against a second baseline – a scale free distribution are underway. Further, key reports are being revised using “color” to quickly identify those nodes whose values are significantly greater than or less than other nodes in the same network on the metric of interest.

Interoperation: ORA is intended to work synergistically with many other tools. Currently ORA can import from many other social network analytic tools, CSV, TSV, and some forms of JSON and can output in CSV, HTML, KML, and is interoperable with many tools such as Analyst Notebook and ArcGIS. Wizards for increased interoperation with technologies that extract social media or do forecasting are currently being developed. APIS to support integration into workflow systems and to support user addition of metrics are planned.
